Package ‘flexclust’

February 19, 2015

Version 1.3-4
Date 2013-07-02
Title Flexible Cluster Algorithms
Depends R (>= 2.14.0), graphics, grid, lattice, modeltools
Imports methods, parallel, stats, stats4
Suggests ellipse, clue, cluster, seriation
Description The main function kcca implements a general framework for
centroids cluster analysis supporting arbitrary distance
measures and centroid computation. Further cluster methods
include hard competitive learning, neural gas, and QT
clustering. There are numerous visualization methods for
cluster results (neighborhood graphs, convex cluster hulls,
barcharts of centroids, ...), and bootstrap methods for the
analysis of cluster stability.

Achievement Test Scores for New Haven Schools

Measurements at the beginning of the 4th grade (when the national average is 4.0) and of the 6th grade in 25 schools in New Haven.

Usage

data(achieve)
Format

A data frame with 25 observations on the following 4 variables.

read4: 4th grade reading
arith4: 4th grade arithmetic
read6: 6th grade reading
arith6: 6th grade arithmetic

Source

http://www.uni-koeln.de/themen/statistik

References

Description

A German manufacturer of premium cars asked customers approximately 3 months after a car purchase which characteristics of the car were most important for the decision to buy the car. The survey was done in 1983 and the data set contains all responses without missing values.

Usage

data(auto)

Format

A data frame with 793 observations on the following 46 variables.

model a factor with levels A B C D, model bought by the customer.
gear a factor with levels 4 gears, 5 econo, 5 sport, or automatic.
leasing a logical vector, was leasing used to finance the car?
usage a factor with levels private, both, business.
previous_model a factor describing which type of car was owned directly before the purchase.
other_consider a factor with levels same manuf, other manuf, both, or none
test_drive a logical vector, did you do a test drive?
info_adv a logical vector, was advertising an important source of information?
info_exp a logical vector, was experience an important source of information?
info_rec a logical vector, were recommendations an important source of information?
ch_clarity a logical vector
ch_economy a logical vector
ch_driving_properties a logical vector
ch_service a logical vector
ch_interior a logical vector
ch_quality a logical vector
ch_technology a logical vector
ch_model_continuity a logical vector
ch_comfort a logical vector
ch_reliability a logical vector
ch_handling a logical vector
ch_reputation a logical vector
ch_concept a logical vector
ch_character a logical vector
ch_power a logical vector
ch_resale_value a logical vector
ch_styling a logical vector
ch_safety a logical vector
ch_sporty a logical vector
ch_consumption a logical vector
ch_space a logical vector
satisfaction a numeric vector describing overall satisfaction (1=very good, 10=very bad).
good1 conception, styling, dimensions.
good2 auto body.
good3 driving and coupled axles.
good4 engine.
good5 electronics.
good6 financing and customer service.
good7 other.
sporty What do you think about the balance of sportiness and comfort? (good more sport more comfort).
drive_char driving characteristics (gentle < speedy < powerful < extreme).
tempo Which average speed do you prefer on German Autobahn in km/h? (< 130 < 130-150 < 150-180 < > 180)
consumption an ordered factor with levels low < ok < high < too high.
gender a factor with levels male female
occupation a factor with levels self-employed, freelance, and employee.
household size of household, an ordered factor with levels 1-2 < >3
Source

The original German data are in the public domain and available at http://dx.doi.org/10.5282/ubm/data.14 from LMU Munich. The variable names and help page were translated to English and converted into Rd format by Friedrich Leisch.

barplot-methods

Barplot/chart Methods in Package ‘flexclust’

Description

Barplot of cluster centers or other cluster statistics.

Usage

## S4 method for signature 'kcca'
barplot(height, bycluster = TRUE, oneplot = TRUE,
data = NULL, FUN=colMeans, main = deparse(substitute(height)),
which = 1:height@k, names.arg = NULL,
oma=par("oma"), col=NULL, mcol="darkred", srt=45, ...)

## S4 method for signature 'kcca'
barchart(x, data, xlab="", strip.labels=NULL,
strip.prefix="Cluster ", col=NULL, mcol="darkred", mlcol=mcol,
which=NULL, legend=FALSE, shade=FALSE, diff=NULL, ...)

Arguments

height, x  An object of class "kcca".
bycluster  If TRUE, then each barplot shows one cluster. If FALSE, then each barplot compares all cluster for one input variable.
oneplot  If TRUE, all barplots are plotted together on one page, else each plot is on a separate page.
data  If not NULL, cluster membership is predicted for the new data and used for the plots. By default the values from the training data are used. Ignored by the barchart method.
FUN  The function to be applied to each cluster for calculating the bar heights. Only used, if data is not NULL.
which          For barplot index number of clusters for the plot, for barchart index numbers or names of variables to plot.
names.arg     A vector of names to be plotted below each bar.
main, oma, xlab, ...     Graphical parameters.
col           Vector of colors for the clusters.
mcol,mlcol    If not NULL, the value of FUN for the complete data set is plotted over each bar as a point with color mcol and a line segment starting in zero with color mlcol.
srt           Number between 0 and 90, rotation of the x-axis labels.
strip.labels  Vector of strings for the strips of the Trellis display.
strip.prefix  Prefix string for the strips of the Trellis display.
legend        If TRUE, the barchart is always plotted on the current graphics device and a legend is added to the bottom of the plot.
shade         If TRUE, only bars with large absolute or relative deviation deviation from the sample mean of the respective variables are plotted in color.
diff          A numerical vector of length two with absolute and relative deviations for shading, default is max/4 absolute deviation and 50% relative deviation.

Note

The flexclust barchart method uses a horizontal arrangements of the bars, and sorts them from top to bottom. Default barcharts in lattice are the other way round (bottom to top). See the examples below how this affects, e.g., manual labels for the y axis.

The barplot method is legacy code and only maintained to keep up with changes in R, all active development is done on barchart.

Friedrich Leisch

References

Examples

c1 <- cclusl(iris[, -5], k=3)
barplot(c1)
barplot(c1, bycluster=FALSE)

## plot the maximum instead of mean value per cluster:
barplot(c1, bycluster=FALSE, data=iris[, -5],
FUN=function(x) apply(x,2,max))

## use lattice for plotting:
barchart(c1)
## birth

`birth` is a dataset containing birth and death rates for 70 countries. The data frame includes two variables:

- **birth**: birth rate (in percent)
- **death**: death rate (in percent)

### Description

Birth and death rates for 70 countries.

### Usage

```r
data(birth)
```

### Format

A data frame with 70 observations on the following 2 variables.

- **birth**: birth rate (in percent)
- **death**: death rate (in percent)

### Source

[http://www.uni-koeln.de/themen/statistik](http://www.uni-koeln.de/themen/statistik)

### References

**Description**

Runs clustering algorithms repeatedly for different numbers of clusters on bootstrap replica of the original data and returns corresponding cluster assignments, centroids and Rand indices comparing pairs of partitions.

**Usage**

`bootFlexclust(x, k, nboot=100, correct=TRUE, seed=NULL, multicore=TRUE, verbose=FALSE, ...)

## S4 method for signature 'bootFlexclust'
summary(object)
## S4 method for signature 'bootFlexclust,missing'
plot(x, y, ...)
## S4 method for signature 'bootFlexclust'
boxplot(x, ...)
## S4 method for signature 'bootFlexclust'
densityplot(x, data, ...)

**Arguments**

- `x, k, ...`: Passed to `stepFlexclust`.
- `nboot`: Number of bootstrap pairs of partitions.
- `correct`: Logical, correct the index for agreement by chance?
- `seed`: If not NULL, a call to `set.seed()` is made before any clustering is done.
- `multicore`: If TRUE, use package `parallel` for parallel processing. In addition, it may be a workstation cluster object as returned by `makeCluster`, see examples below.
- `verbose`: If TRUE, show progress information during computations. Will not work with `multicore=TRUE`.
- `y, data`: Not used.
- `object`: An object of class "bootFlexclust".

**Details**

Availability of `multicore` is checked when `flexclust` is loaded and stored in `getOption("flexclust")$have_multicore`. Set to FALSE for debugging and more sensible error messages in case something goes wrong.

Examples

## Not run:

## data uniform on unit square
x <- matrix(runif(400), ncol=2)

c1 <- FALSE

## to run bootstrap replications on a workstation cluster do the following:
library("parallel")
c1 <- makeCluster(2, type = "PSOCK")
c1 <- clusterCall(c1, function() require("flexclust"))

## 50 bootstrap replicates for speed in example,
## use more for real applications
bcl <- bootFlexclust(x, k=2:7, nboot=50, FUN=cclust, multicore=c1)

bcl
summary(bcl)

## splitting the square into four quadrants should be the most stable
## solution (increase nboot if not)
plot(bcl)
densityplot(bcl, from=0)

## End(Not run)

---

**bundestag**

*German Parliament Election Data*

**Description**

Results of the elections 2002, 2005 or 2009 for the German Bundestag, the first chamber of the German parliament.

**Usage**

data(btw2002)
data(btw2005)
data(btw2009)
bundestag(year, second=TRUE, percent=TRUE, nzero=TRUE, state=FALSE)
Arguments

- **year**: numeric or character, year of the election.
- **second**: logical, return second or first votes?
- **percent**: logical, return percentages or absolute numbers?
- **nазero**: logical, convert NAs to 0?
- **state**: logical or character. If TRUE then only column state from the corresponding data frame is returned, and all other arguments are ignored. If character, then it is used as pattern to grep for the corresponding state(s), see examples.

Format

`btw200x` are data frames with 299 rows (corresponding to constituencies) and 17 columns. All columns except `state` are numeric.

- **state**: factor, the 16 German federal states.
- **eligible**: number of citizens eligible to vote.
- **votes**: number of eligible citizens who did vote.
- **invalid1, invalid2**: number of invalid first and second votes (see details below).
- **valid1, valid2**: number of valid first and second votes.
- **SPD1, SPD2**: number of first and second votes for the Social Democrats.
- **UNION1, UNION2**: number of first and second votes for CDU/CSU, the conservative Christian Democrats.
- **GRUENE1, GRUENE2**: number of first and second votes for the Green Party.
- **FDP1, FDP2**: number of first and second votes for the Liberal Party.
- **LINKE1, LINKE2**: number of first and second votes for the Left Party (PDS in 2002).

Missing values indicate that a party did not candidate in the corresponding constituency.

Details

`btw200x` are the original data sets. `bundestag()` is a helper function which extracts first or second votes, calculates percentages (number of votes for a party divided by number of valid votes), replaces missing values by zero, and converts the result from a data frame to a matrix. By default it returns the percentage of second votes for each party, which determines the number of seats each party gets in parliament.

German Federal Elections

Half of the Members of the German Bundestag are elected directly from Germany’s 299 constituencies, the other half on the parties’ state lists. Accordingly, each voter has two votes in the elections to the German Bundestag. The first vote, allowing voters to elect their local representatives to the Bundestag, decides which candidates are sent to Parliament from the constituencies.

The second vote is cast for a party list. And it is this second vote that determines the relative strengths of the parties represented in the Bundestag. At least 598 Members of the German Bundestag are elected in this way. In addition to this, there are certain circumstances in which some candidates win what are known as “overhang mandates” when the seats are being distributed.
References

Homepage of the Bundestag: http://www.bundestag.de

Examples

```r
p02 <- bundestag(2002)
pairs(p02)
p05 <- bundestag(2005)
pairs(p05)
p09 <- bundestag(2009)
pairs(p09)

state <- bundestag(2002, state=TRUE)
table(state)

start.with.b <- bundestag(2002, state="B")
table(start.with.b)

pairs(p09, col=2-(state="Bayern"))
```

Description

Separate boxplot of variables in each cluster in comparison with boxplot for complete sample.

Usage

```r
## S4 method for signature 'kcca'
bwplot(x, data, xlab="",
       strip.labels=NULL, strip.prefix="Cluster ",
       col=NULL, shade=!is.null(shadefun), shadefun=NULL, ...)
```

Arguments

- **x**: An object of class "kcca".
- **data**: If not NULL, cluster membership is predicted for the new data and used for the plots. By default the values from the training data are used.
- **xlab, ...**: Graphical parameters.
- **col**: Vector of colors for the clusters.
- **strip.labels**: Vector of strings for the strips of the Trellis display.
- **strip.prefix**: Prefix string for the strips of the Trellis display.
- **shade**: If TRUE, only boxes with larger deviation from the median or quartiles of the total population of the respective variables are filled with color.
- **shadefun**: A function or name of a function to compute which boxes are shaded, e.g. "medianInside" (default) or "boxOverlap".
**Examples**

```r
set.seed(1)
c <- cclus(iris[, -5], k=3, save.data=TRUE)
bwplot(cl)

## fill only boxes with color which do not contain the overall median
## (grey dot of background box)
bwplot(cl, shade=TRUE)

## fill only boxes with color which do not overlap with the box of the
## complete sample (grey background box)
bwplot(cl, shadefun="boxOverlap")
```

---

**cclus**  
*Convex Clustering*

---

**Description**

Perform k-means clustering, hard competitive learning or neural gas on a data matrix.

**Usage**

```r
cclus(x, k, dist = "euclidean", method = "kmeans",
      weights=NULL, control=NULL, group=NULL, simple=FALSE,
      save.data=FALSE)
```

**Arguments**

- **x**: A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
- **k**: Either the number of clusters, or a vector of cluster assignments, or a matrix of initial (distinct) cluster centroids. If a number, a random set of (distinct) rows in x is chosen as the initial centroids.
- **dist**: Distance measure, one of "euclidean" (mean square distance) or "manhattan" (absolute distance).
- **method**: Clustering algorithm: one of "kmeans", "hardcl" or "neuralgas", see details below.
- **weights**: An optional vector of weights to be used in the fitting process. Works only in combination with hard competitive learning.
- **control**: An object of class cclusControl.
- **group**: Currently ignored.
- **simple**: Return an object of class kccasimple?
- **save.data**: Save a copy of x in the return object?
Details

This function uses the same computational engine as the earlier function of the same name from package 'cclust'. The main difference is that it returns an S4 object of class "kcca", hence all available methods for "kcca" objects can be used. By default kcca and cclust use exactly the same algorithm, but cclust will usually be much faster because it uses compiled code.

If dist is "euclidean", the distance between the cluster center and the data points is the Euclidian distance (ordinary kmeans algorithm), and cluster means are used as centroids. If "manhattan", the distance between the cluster center and the data points is the sum of the absolute values of the distances, and the column-wise cluster medians are used as centroids.

If method is "kmeans", the classic kmeans algorithm as given by MacQueen (1967) is used, which works by repeatedly moving all cluster centers to the mean of their respective Voronoi sets. If "hardcl", on-line updates are used (AKA hard competitive learning), which work by randomly drawing an observation from x and moving the closest center towards that point (e.g., Ripley 1996). If "neuralgas" then the neural gas algorithm by Martinetz et al (1993) is used. It is similar to hard competitive learning, but in addition to the closest centroid also the second closest centroid is moved in each iteration.

Value

An object of class "kcca".

Examples

```r
## a 2-dimensional example
x<-rbind(matrix(rnorm(100,sd=0.3),ncol=2),
          matrix(rnorm(100,mean=1,sd=0.3),ncol=2))
cl<-cclust(x,2)
predict(x, cl)
points(cl@centers, pch="x", cex=2, col=3)
```
## a 3-dimensional example

```r
x <- rbind(matrix(rnorm(150, sd=0.3), ncol=3),
            matrix(rnorm(150, mean=2, sd=0.3), ncol=3),
            matrix(rnorm(150, mean=4, sd=0.3), ncol=3))
cl <- cclust(x, 6, method="neuralgas", save.data=TRUE)
pairs(x, col=predict(cl))
plot(cl)
```

---

### clusterSim

---

#### Description

Returns a matrix of cluster similarities. Currently two methods for computing similarities of clusters are implemented, see details below.

#### Usage

```r
## S4 method for signature 'kcca'
clusterSim(object, data= NULL, method=c("shadow", "centers"),
            symmetric=FALSE, ...)

## S4 method for signature 'kccasimple'
clusterSim(object, data= NULL, method=c("shadow", "centers"),
            symmetric=FALSE, ...)
```

#### Arguments

- `object` : fitted object.
- `data` : Data to use for computation of the shadow values. If the cluster object `x` was created with `save.data=TRUE`, then these are used by default. Ignored if `method="centers".
- `method` : Type of similarities, see details below.
- `symmetric` : Compute symmetric or asymmetric shadow values? Ignored if `method="centers".
- `...` : currently not used.

#### Details

If `method="shadow"` (the default), then the similarity of two clusters is proportional to the number of points in a cluster, where the centroid of the other cluster is second-closest. See Leisch (2006, 2008) for detailed formulas.

If `method="centers"`, then first the pairwise distances between all centroids are computed and rescaled to [0,1]. The similarity between two clusters is then simply 1 minus the rescaled distance.

#### Author(s)

Friedrich Leisch

Examples

example(Nclus)

clusterSim(cl)
clusterSim(cl, symmetric=TRUE)

## should have similar structure but will be numerically different:
clusterSim(cl, symmetric=TRUE, data=Nclus[sample(1:550, 200),])

## different concept of cluster similarity
clusterSim(cl, method="centers")

conversion

Conversion Between S3 Partition Objects and KCCA

Description

These functions can be used to convert the results from cluster functions like kmeans or pam to objects of class "kcca" and vice versa

Usage

as.kcca(object, ...)

## S3 method for class 'hclust'
as.kcca(object, data, k, family=NULL, save.data=FALSE, ...)

## S3 method for class 'kmeans'
as.kcca(object, data, save.data=FALSE, ...)

## S3 method for class 'partition'
as.kcca(object, data=NULL, save.data=FALSE, ...)

## S3 method for class 'skmeans'
as.kcca(object, data, save.data=FALSE, ...)

## S4 method for signature 'kccasimple,kmeans'
coerce(from, to="kmeans", strict=TRUE)
Arguments

- **object**: fitted object.
- **data**: data which were used to obtain the clustering. For "partition" objects created by functions from package cluster this is optional, if object contains the data.
- **save.data**: Save a copy of the data in the return object?
- **k**: number of clusters.
- **family**: object of class kccaFamily, can be omitted for some known distances.
- **...** currently not used.
- **from, to, strict** usual arguments for **coerce**

Details

For hierarchical clustering the cluster memberships of the converted object can be different from the result of **cutree**, because one KCCA-iteration has to be performed in order to obtain a valid kcca object. In this case a warning is issued.

Author(s)

Friedrich Leisch

Examples

```
data(Nclus)

cl1 <- kmeans(Nclus, 4)
cl1
cl1a <- as.kcca(cl1, Nclus)
cl1a
cl1b <- as(cl1a, "kmeans")

library("cluster")
cl2 <- pam(Nclus, 4)
cl2
cl2a <- as.kcca(cl2)
cl2a
## the same
cl2b = as.kcca(cl2, Nclus)
cl2b

## hierarchical clustering
hc <- hclust(dist(USArrests))
plot(hc)
rect.hclust(hc, k=3)
c3 <- cutree(hc, k=3)
```
Dentition of Mammals

**Description**

Mammal’s teeth divided into the 4 groups: incisors, canines, premolars and molars.

**Usage**

`data(dentitio)`

**Format**

A data frame with 66 observations on the following 8 variables.

- **top.inc**: top incisors
- **bot.inc**: bottom incisors
- **top.can**: top canines
- **bot.can**: bottom canines
- **top.pre**: top premolars
- **bot.pre**: bottom premolars
- **top.mol**: top molars
- **bot.mol**: bottom molars

**Source**

[http://www.uni-koeln.de/themen/statistik](http://www.uni-koeln.de/themen/statistik)

**References**

Compute pairwise distances between two data sets

**Description**

This function computes and returns the distance matrix computed by using the specified distance measure to compute the pairwise distances between the rows of two data matrices.

**Usage**

```r
dist2(x, y, method = "euclidean", p=2)
```

**Arguments**

- `x`: A data matrix.
- `y`: A vector or second data matrix.
- `method`: the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- `p`: The power of the Minkowski distance.

**Details**

This is a two-data-set equivalent of the standard function `dist`. It returns a matrix of all pairwise distances between rows in `x` and `y`. The current implementation is efficient only if `y` has not too many rows (the code is vectorized in `x` but not in `y`).

**Author(s)**

Friedrich Leisch

**See Also**

`dist`

**Examples**

```r
x = matrix(rnorm(20), ncol=4)
rownames(x) = paste("X", 1:nrow(x), sep=".")
y = matrix(rnorm(12), ncol=4)
rownames(y) = paste("Y", 1:nrow(y), sep=".")

dist2(x, y)
dist2(x, y, "man")

data(milk)
dist2(milk[1:5,], milk[4:6,])
```
**distances**  
*Distance and Centroid Computation*

**Description**  
Helper functions to create *kccaFamily* objects.

**Usage**

- `distAngle(x, centers)`
- `distCanberra(x, centers)`
- `distCor(x, centers)`
- `distEuclidean(x, centers)`
- `distJaccard(x, centers)`
- `distManhattan(x, centers)`
- `distMax(x, centers)`
- `distMinkowski(x, centers, p=2)`

- `centAngle(x)`
- `centMean(x)`
- `centMedian(x)`

- `centOptim(x, dist)`
- `centOptim01(x, dist)`

**Arguments**

- **x**  
  A data matrix.

- **centers**  
  A matrix of centroids.

- **p**  
  The power of the Minkowski distance.

- **dist**  
  A distance function.

**Author(s)**

Friedrich Leisch

---

**flexclustControl-class**

*Classes "flexclustControl" and "cclustControl"*

**Description**

Hyperparameters for cluster algorithms.
Objects from the Class

Objects can be created by calls of the form `new("flexclustControl", ...`). In addition, named lists can be coerced to `flexclustControl` objects, names are completed if unique (see examples).

Slots

Objects of class `flexclustControl` have the following slots:

- `iter.max`: Maximum number of iterations.
- `tolerance`: The algorithm is stopped when the (relative) change of the optimization criterion is smaller than `tolerance`.
- `verbose`: If a positive integer, then progress is reported every `verbose` iterations. If 0, no output is generated during model fitting.
- `classify`: Character string, one of "auto", "weighted", "hard" or "simann".
- `initcent`: Character string, name of function for initial centroids, currently "randomcent" (the default) and "kmeanspp" are available.
- `gamma`: Gamma value for weighted hard competitive learning.
- `simann`: Parameters for simulated annealing optimization (only used when `classify="simann"`).
- `ntry`: Number of trials per iteration for QT clustering.
- `min.size`: Clusters smaller than this value are treated as outliers.

Objects of class `cclustControl` inherit from `flexclustControl` and have the following additional slots:

- `method`: Learning rate for hard competitive learning, one of "polynomial" or "exponential".
- `pol.rate`: Positive number for polynomial learning rate of form \( 1/\text{iter} \times \text{par} \).
- `exp.rate`: Vector of length 2 with parameters for exponential learning rate of form \( \text{par}1 \times (\text{par}2/\text{par}1)^{\text{iter}/\text{iter.max}} \).
- `ng.rate`: Vector of length 4 with parameters for neural gas, see details below.

Learning Rate of Neural Gas

The neural gas algorithm uses updates of form

\[
  \text{cnew} = \text{cold} + e \times \exp(-m/l) \times (x - \text{cold})
\]

for every centroid, where \( m \) is the order (minus 1) of the centroid with respect to distance to data point \( x \) (0=closest, 1=second, ...). The parameters \( e \) and \( l \) are given by

\[
  e = \text{par}1 \times (\text{par}2/\text{par}1)^{\text{iter}/\text{iter.max}},
\]

\[
  l = \text{par}3 \times (\text{par}4/\text{par}3)^{\text{iter}/\text{iter.max}}.
\]

See Martinetz et al (1993) for details of the algorithm, and the examples section on how to obtain default values.

`kcca`, `cclus`

**Examples**

```r
## have a look at the defaults
new("flexclustControl")

## corce a list
mycont = list(iter=500, tol=0.001, class="w")
as(mycont, "flexclustControl")

## some additional slots
as(mycont, "cclusControl")

## default values for ng.rate
new("cclusControl")@ng.rate
```

---

**flxColors**

*Flexclust Color Palettes*

**Description**

Create and access palettes for the plot methods.

**Usage**

```r
flxColors(n=1:8, color=c("full","medium", "light","dark"), grey=FALSE)
```

**Arguments**

- `n` Index number of color to return (1 to 8)
- `color` Type of color, see details.
- `grey` Return grey value corresponding to palette.

**Details**

This function creates color palettes in HCL space for up to 8 colors. All palettes have constant chroma and luminance, only the hue of the colors change within a palette. Palettes "full" and "dark" have the same luminance, and palettes "medium" and "light" have the same luminance.

Examples

```r
opar <- par(c("mfrow", "mar", "xaxt"))
par(mfrow=c(2,2), mar=c(0,0,2,0), yaxt="n")

x <- rep(1, 8)

barplot(x, col = flxColors(color="full"), main="full")
barplot(x, col = flxColors(color="dark"), main="dark")
barplot(x, col = flxColors(color="medium"), main="medium")
barplot(x, col = flxColors(color="light"), main="light")

par(opar)
```

Description
Image plot of cluster segments overlaid by neighbourhood graph.

Usage

```r
## S4 method for signature 'kcca'
image(x, which = 1:2, npoints = 100,
      xlab = "", ylab = "", fastcol = TRUE, col=NULL,
      clwd=0, graph=TRUE, ...)
```

Arguments

- `x` An object of class "kcca".
- `which` Index number of dimensions of input space to plot.
- `npoints` Number of grid points for image.
- `fastcol` If TRUE, a greedy algorithm is used for the background colors of the segments, which may result in neighbouring segments having the same color. If FALSE, neighbouring segments always have different colors at a speed penalty.
- `col` Vector of background colors for the segments.
- `clwd` Line width of contour lines at cluster boundaries, use larger values for npoints than the default to get smooth lines. (Warning: We really need a smarter way to draw cluster boundaries!)
Logical, add a neighborhood graph to the plot?

Graphical parameters.

Details

This works only for "kcca" objects, no method is available for "kccasimple" objects.

kcca

Get Information on Fitted Flexclust Objects

Description

Returns descriptive information about fitted flexclust objects like cluster sizes or sum of within-cluster distances.

Usage

## S4 method for signature 'flexclust,character'
info(object, which, drop=TRUE, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>fitted object.</td>
</tr>
<tr>
<td>which</td>
<td>which information to get. Use which=&quot;help&quot; to list available information.</td>
</tr>
<tr>
<td>drop</td>
<td>logical. If TRUE the result is coerced to the lowest possible dimension.</td>
</tr>
<tr>
<td>...</td>
<td>passed to methods.</td>
</tr>
</tbody>
</table>

Details

Function info can be used to access slots of fitted flexclust objects in a portable way, and in addition computes some meta-information like sum of within-cluster distances.

Function infoCheck returns a logical value that is TRUE if the requested information can be computed from the object.

kcca

K-Centroids Cluster Analysis

Description

Perform k-centroids clustering on a data matrix.
Usage

kcca(x, k, family=kccaFamily("kmeans"), weights=NULL, group=NULL, control=NULL, simple=FALSE, save.data=FALSE)
kccaFamily(which=NULL, dist=NULL, cent=NULL, name=which, preproc = NULL, trim=0, groupFun = "minSumClusters")

## S4 method for signature 'kccasimple'
summary(object)

Arguments

x
A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
k
Either the number of clusters, or a vector of cluster assignments, or a matrix of initial (distinct) cluster centroids. If a number, a random set of (distinct) rows in x is chosen as the initial centroids.
family
Object of class kccaFamily.
weights
An optional vector of weights to be used in the clustering process, cannot be combined with all families.
group
An optional grouping vector for the data, see details below.
control
An object of class flexclustControl.
simple
Return an object of class kccasimple?
save.data
Save a copy of x in the return object?
which
One of "kmeans", "kmedians", "angle", "jaccard", or "ejaccard".
name
Optional long name for family, used only for show methods.
dist
A function for distance computation, ignored if which is specified.
cent
A function for centroid computation, ignored if which is specified.
preproc
Function for data preprocessing.
trim
A number in between 0 and 0.5, if non-zero then trimmed means are used for the kmeans family, ignored by all other families.
groupFun
Function or name of function to obtain clusters for grouped data, see details below.
object
Object of class "kcca".

Details

See the paper A Toolbox for K-Centroids Cluster Analysis referenced below for details.

Value

Function kcca returns objects of class "kcca" or "kccasimple" depending on the value of argument simple. The simpler objects contain fewer slots and hence are faster to compute, but contain no auxiliary information used by the plotting methods. Most plot methods for "kccasimple" objects do nothing and return a warning. If only centroids, cluster membership or prediction for new data are of interest, then the simple objects are sufficient.
**Predefined Families**

Function `kccaFamily()` currently has the following predefined families (distance / centroid):

- **kmeans**: Euclidean distance / mean
- **kmedians**: Manhattan distance / median
- **angle**: angle between observation and centroid / standardized mean
- **jaccard**: Jaccard distance / numeric optimization
- **ejaccard**: Jaccard distance / mean

See Leisch (2006) for details on all combinations.

**Group Constraints**

If `group` is not NULL, then observations from the same group are restricted to belong to the same cluster (must-link constraint) or different clusters (cannot-link constraint) during the fitting process. If `groupFun = "minSumClusters"`, then all group members are assign to the cluster where the center has minimal average distance to the group members. If `groupFun = "majorityClusters"`, then all group members are assigned to the cluster the majority would belong to without a constraint.

`groupFun = "differentClusters"` implements a cannot-link constraint, i.e., members of one group are not allowed to belong to the same cluster. The optimal allocation for each group is found by solving a linear sum assignment problem using `solve_LSAP`. Obviously the group sizes must be smaller than the number of clusters in this case.

Ties are broken at random in all cases. Note that at the moment not all methods for fitted "kcca" objects respect the grouping information, most importantly the plot method when a data argument is specified.

**kcca2df**

*Convert Cluster Result to Data Frame*

**Description**

Convert object of class "kcca" to a data frame in long format.

**Usage**

kcca2df(object, data)

**Arguments**

- **object**: Object of class "kcca".
- **data**: Optional data if not saved in object.

**Value**

A data.frame with columns value, variable and group.
Examples

```r
c.iris <- cclust(iris[,-5], 3, save.data=TRUE)
df.c.iris <- kcca2df(c.iris)
summary(df.c.iris)
densityplot(~value|variable+group, data=df.c.iris)
```

milk

### Milk of Mammals

**Description**

The data set contains the ingredients of mammal’s milk of 25 animals.

**Usage**

```r
data(milk)
```

**Format**

A data frame with 25 observations on the following 5 variables (all in percent).

- **water**: water
- **protein**: protein
- **fat**: fat
- **lactose**: lactose
- **ash**: ash

Artificial Example with 4 Gaussians

Description
A simple artificial regression example with 4 clusters, all of them having a Gaussian distribution.

Usage
data(Nclus)

Details
The Nclus data set can be re-created by loading package flexmix and running ExNclus(100) using set.seed(2602). It has been saved as a data set for simplicity of examples only.

Examples
data(Nclus)
c1 <- cclus(Nclus, k=4, simple=FALSE, save.data=TRUE)
plot(c1)

nutrient

Nutrients in Meat, Fish and Fowl

Description
The data set contains the measurements of nutrients in several types of meat, fish and fowl.

Usage
data(nutrient)

Format
A data frame with 27 observations on the following 5 variables.

energy: food energy (calories)
protein: protein (grams)
fat: fat (grams)
calcium: calcium (milli grams)
iron: iron (milli grams)

pairs-methods  

Methods for Function pairs in Package ‘flexclust’

Description

Plot a matrix of neighbourhood graphs.

Usage

```r
## S4 method for signature 'kcca'
pairs(x, which=NULL, project=NULL, oma=NULL, ...)
```

Arguments

- `x`: an object of class "kcca"
- `which`: Index numbers of dimensions of (projected) input space to plot, default is to plot all dimensions.
- `project`: Projection object for which a `predict` method exists, e.g., the result of `prcomp`.
- `oma`: Outer margin.
- `...`: Passed to the `plot` method.

Details

This works only for "kcca" objects, no method is available for "kccasimple" objects.

Author(s)

Friedrich Leisch

parameters

Get Centroids from KCCA Object

Description

Returns the matrix of centroids of a fitted object of class "kcca".

Usage

```r
## S4 method for signature 'kccasimple'
parameters(object, ...)
```
Arguments

- **object**: fitted object.
- **...**: currently not used.

Author(s)

Friedrich Leisch

---

**Description**

Plot the neighbourhood graph of a cluster solution together with projected data points.

**Usage**

```r
## S4 method for signature 'kcca,missing'
plot(x, y, which=1:2, project=NULL,
     data=NULL, points=TRUE, hull=TRUE, hull.args=NULL,
     number = TRUE, simlines=TRUE,
     lwd=1, maxlwd=8*lwd, cex=1.5, numcol=FALSE, nodes=16,
     add=FALSE, xlab="", ylab="", xlim = NULL,
     ylim = NULL, pch=NULL, col=NULL, ...)```

**Arguments**

- **x**: an object of class "kcca"
- **y**: not used
- **which**: Index numbers of dimensions of (projected) input space to plot.
- **project**: Projection object for which a predict method exists, e.g., the result of `prcomp`.
- **data**: Data to include in plot. If the cluster object `x` was created with `save.data=TRUE`, then these are used by default.
- **points**: Logical, shall data points be plotted (if available)?
- **hull**: If TRUE, then hulls of the data are plotted (if available). Can either be a logical value, one of the strings "convex" (the default) or "ellipse", or a function for plotting the hulls.
- **hull.args**: A list of arguments for the hull function.
- **number**: Logical, plot number labels in nodes of graph?
- **numcol, cex**: Color and size of number labels in nodes of graph. If `numcol` is logical, it switches between black and the color of the clusters, else it is taken as a vector of colors.
- **nodes**: Plotting symbol to use for nodes if no numbers are drawn.
**simlines** Logical, plot edges of graph?

**lwd, maxlwd** Numerical, thickness of lines.

**add** Logical, add to existing plot?

**xlab, ylab** Axis labels.

**xlim, ylim** Axis range.

**pch, col, ...** Plotting symbols and colors for data points.

**Details**

This works only for "kcca" objects, no method is available for "kccasimple" objects.

**Author(s)**

Friedrich Leisch

**References**

**predict-methods**

**Predict Cluster Membership**

**Description**

Return either the cluster membership of training data or predict for new data.

**Usage**

```r
# S4 method for signature 'kccasimple'
predict(object, newdata, ...)
# S4 method for signature 'flexclust,ANY'
clusters(object, newdata, ...)
```

**Arguments**

- **object** Object of class inheriting from "flexclust".
- **newdata** An optional data matrix with the same number of columns as the cluster centers. If omitted, the fitted values are used.
- **...** Currently not used.
Details

clusters can be used on any object of class "flexclust" and returns the cluster memberships of the training data.

predict can be used only on objects of class "kcca" (which inherit from "flexclust"). If no newdata argument is specified, the function is identical to clusters, if newdata is specified, then cluster memberships for the new data are predicted. clusters(object, newdata, ...) is an alias for predict(object, newdata, ...).

priceFeature Artificial 2d Market Segment Data

Description

Simple artificial 2-dimensional data to demonstrate clustering for market segmentation. One dimension is the hypothetical feature sophistication (or performance or quality, etc) of a product, the second dimension the price customers are willing to pay for the product.

Usage

priceFeature(n, which=c("2clust", "3clust", "5clust", "ellipse", "triangle", "circle", "square", "largesmall"))

Arguments

n sample size
which shape of data set

References

Examples

plot(priceFeature(200, "2clust"))
plot(priceFeature(200, "3clust"))
plot(priceFeature(200, "5clust"))
plot(priceFeature(200, "ell"))
plot(priceFeature(200, "tri"))
plot(priceFeature(200, "circ"))
plot(priceFeature(200, "square"))
plot(priceFeature(200, "largesmall"))
projAxes

Add Arrows for Projected Axes to a Plot

Description

Adds arrows for original coordinate axes to a projection plot.

Usage

projAxes(object, which=1:2, center=NULL,
          col="red", radius=NULL,
          minradius=0.1, textargs=list(col=col),
          col.names=getColnames(object),
          which.names="", group = NULL, groupFun = colMeans,
          plot=TRUE, ...)

placeLabels(object)

## S4 method for signature 'projAxes'
placeLabels(object)

Arguments

object Return value of a projection method like prcomp.
which Index number of dimensions of (projected) input space that have been plotted.
center Center of the coordinate system to use in projected space. Default is the center of the plotting region.
col Color of arrows.
radius Relative size of the arrows.
minradius Minimum radius of arrows to include (relative to arrow size).
textargs List of arguments for text.
col.names Variable names of the original data.
which.names A regular expression which variable names to include in the plot.
group An optional grouping variable for the original coordinates. Coordinates with group NA are omitted.
groupFun Function used to aggregate the projected coordinates if group is specified.
plot Logical, if TRUE the axes are added to the current plot.
... Passed to arrows.

Value

projAxes invisibly returns an object of class "projAxes", which can be added to an existing plot by its plot method.
Author(s)

Friedrich Leisch

Examples

data(milk)
milk.pca <- prcomp(milk, scale=TRUE)

## create a biplot step by step
plot(predict(milk.pca), type="n")
text(predict(milk.pca), rownames(milk), col="green", cex=0.8)
projAxes(milk.pca)

## the same, but arrows are blue, centered at origin and all arrows are
## plotted
plot(predict(milk.pca), type="n")
text(predict(milk.pca), rownames(milk), col="green", cex=0.8)
projAxes(milk.pca, col="blue", center=0, minradius=0)

## use points instead of text, plot PC2 and PC3, manual radius
## specification, store result
plot(predict(milk.pca)[,c(2,3)])
arr <- projAxes(milk.pca, which=c(2,3), radius=1.2, plot=FALSE)
plot(arr)

## Not run:

## manually try to find new places for the labels: each arrow is marked
## active in turn, use the left mouse button to find a better location
## for the label. Use the right mouse button to go on to the next
## variable.
arr1 <- placeLabels(arr)

## now do the plot again:
plot(predict(milk.pca)[,c(2,3)])
plot(arr1)

## End(Not run)

propBarchart

---

**Description**

Split a binary or numeric matrix by a grouping variable, run a series of tests on all variables, adjust for multiple testing and graphically represent results.
Usage

propBarchart(x, g, alpha=0.05, correct="holm", test="prop.test",
           sort=FALSE, strip.prefix="", strip.labels=NULL,
           which=NULL, ...)

## S4 method for signature 'propBarchart'
summary(object, ...)

groupBWplot(x, g, alpha=0.05, correct="holm", col=NULL,
            shade=!is.null(shadefun), shadefun=NULL,
            strip.prefix="", strip.labels=NULL, which=NULL, ...)

Arguments

x      A binary data matrix.
g      A factor specifying the groups.
alpha  Significance level for test of differences in proportions.
correct Correction method for multiple testing, passed to p.adjust.
test   Test to use for detecting significant differences in proportions.
sort   Logical, sort variables by total sample mean?
strip.prefix Character string prepended to strips of the barchart (the remainder of the strip are group levels and group sizes). Ignored if strip.labels is specified.
strip.labels Character vector of labels to use for strips of barchart.
which   Index numbers or names of variables to plot.
...     Passed on to barchart or bwplot.
object  Return value of propBarchart.
col     Vector of colors for the panels.
shade   If TRUE, only variables with significant differences in median are filled with color.
shadefun A function or name of a function to compute which boxes are shaded, e.g. "kruskalTest" (default), "medianInside" or "boxOverlap".

Details

Function propBarchart splits a binary data matrix into subgroups, computes the percentage of ones in each column and compares the proportions in the groups using prop.test. The p-values for all variables are adjusted for multiple testing and a barchart of group percentages is drawn highlighting variables with significant differences in proportion. The summary method can be used to create a corresponding table for publications.

Function groupBWplot takes a general numeric matrix, also splits into subgroups and uses boxes instead of bars. By default kruskal.test is used to compute significant differences in location, in addition the heuristics from bwplot,kcca-method can be used. Boxes of the complete sample are used as reference in the background.

groupBWplot(x, iris$Species, shade = TRUE)
groupBWplot(x, iris$Species, shadefun = "medianInside")

qtclust

Stochastic QT Clustering

Description

Perform stochastic QT clustering on a data matrix.

Usage

qtclust(x, radius, family = kccaFamily("kmeans"), control = NULL,
        save.data = FALSE, kcca = FALSE)

Arguments

x A numeric matrix of data, or an object that can be coerced to such a matrix (such
    as a numeric vector or a data frame with all numeric columns).
radius Maximum radius of clusters.
family Object of class kccaFamily specifying the distance measure to be used.
control An object of class flexclustControl specifying the minimum number of ob-
        servations per cluster (min.size), and trials per iteration (ntry, see details be-
        low).
save.data Save a copy of x in the return object?
kcca Run kcca after the QT cluster algorithm has converged?
Details

This function implements a variation of the QT clustering algorithm by Heyer et al. (1999), see Scharl and Leisch (2006). The main difference is that in each iteration not all possible cluster start points are considered, but only a random sample of size control@ntry. We also consider only points as initial centers where at least one other point is within a circle with radius radius. In most cases the resulting solutions are almost the same at a considerable speed increase, in some cases even better solutions are obtained than with the original algorithm. If control@ntry is set to the size of the data set, an algorithm similar to the original algorithm as proposed by Heyer et al. (1999) is obtained.

Value

Function qtclust by default returns objects of class "kccasimple". If argument kcca is TRUE, function kcca() is run afterwards (initialized on the QT cluster solution). Data points not clustered by the QT cluster algorithm are omitted from the kcca() iterations, but filled back into the return object. All plot methods defined for objects of class "kcca" can be used.

## maximum distrance of point to cluster center is 1
## -> more clusters, longer runtime
cl2 <- qtclust(x, radius=1)

opar <- par(c("mfrow","mar"))
par(mfrow=c(2,1), mar=c(2.1,2.1,1,1))
plot(x, col=predict(cl1), xlab="", ylab="")
plot(x, col=predict(cl2), xlab="", ylab="")
par(opar)
Description

Compute the (adjusted) Rand, Jaccard and Fowlkes-Mallows index for agreement of two partitions.

Usage

comPart(x, y, type=c("ARI","RI","J","FM"))

## S4 method for signature 'flexclust,flexclust'
comPart(x, y, type)

## S4 method for signature 'numeric,numeric'
comPart(x, y, type)

## S4 method for signature 'flexclust,numeric'
comPart(x, y, type)

## S4 method for signature 'numeric,flexclust'
comPart(x, y, type)

randIndex(x, y, correct=TRUE, original=!correct)

## S4 method for signature 'table,missing'
randIndex(x, y, correct=TRUE, original=!correct)

## S4 method for signature 'ANY,ANY'
randIndex(x, y, correct=TRUE, original=!correct)

Arguments

x Either a 2-dimensional cross-tabulation of cluster assignments (for randIndex only), an object inheriting from class "flexclust", or an integer vector of cluster memberships.

y An object inheriting from class "flexclust", or an integer vector of cluster memberships.

type character vector of abbreviations of indices to compute.

correct, original Logical, correct the Rand index for agreement by chance?

Value

A vector of indices.

Rand Index

Let \( A \) denote the number of all pairs of data points which are either put into the same cluster by both partitions or put into different clusters by both partitions. Conversely, let \( D \) denote the number of all pairs of data points that are put into one cluster in one partition, but into different clusters by the other partition. The partitions disagree for all pairs \( D \) and agree for all pairs \( A \). We can measure
the agreement by the Rand index $A/(A + D)$ which is invariant with respect to permutations of cluster labels.

The index has to be corrected for agreement by chance if the sizes of the clusters are not uniform (which is usually the case), or if there are many clusters, see Hubert & Arabie (1985) for details.

**Jaccard Index**

If the number of clusters is very large, then usually the vast majority of pairs of points will not be in the same cluster. The Jaccard index tries to account for this by using only pairs of points that are in the same cluster in the definition of $A$.

**Fowlkes-Mallows**

Let $A$ again be the pairs of points that are in the same cluster in both partitions. Fowlkes-Mallows divides this number by the geometric mean of the sums of the number of pairs in each cluster of the two partitions. This gives the probability that a pair of points which are in the same cluster in one partition are also in the same cluster in the other partition.

**Examples**

```r
## no class correlations: corrected Rand almost zero
g1 <- sample(1:5, size=1000, replace=TRUE)
g2 <- sample(1:5, size=1000, replace=TRUE)
tab <- table(g1, g2)
randIndex(tab)

## uncorrected version will be large, because there are many points
## which are assigned to different clusters in both cases
randIndex(tab, correct=FALSE)
comPart(g1, g2)

## let pairs (g1=1, g2=1) and (g1=3, g2=3) agree better
k <- sample(1:1000, size=200)
g1[k] <- 1
g2[k] <- 1
k <- sample(1:1000, size=200)
g1[k] <- 3
g2[k] <- 3
tab <- table(g1, g2)
```
randomTour

Plot a Random Tour

Description

Create a series of projection plots corresponding to a random tour through the data.

Usage

randomTour(object, ...)

## S4 method for signature 'ANY'
randomTour(object, ...)

## S4 method for signature 'matrix'
randomTour(object, ...)

## S4 method for signature 'flexclust'
randomTour(object, data=NULL, col=NULL, ...)

randomTourMatrix(x, directions=10,
                 steps=100, sec=4, sleep = sec/steps,
                 axiscol=2, axislab=colnames(x),
                 center=NULL, radius=1, minradius=0.01, asp=1,
                 ...)

Arguments

object, x  A matrix or an object of class "flexclust".
data  Data to include in plot.
col  Plotting colors for data points.
directions  Integer value, how many different directions are toured.
steps  Integer, number of steps in each direction.
sec  Numerical, lower bound for the number of seconds each direction takes.
sleep  Numerical, sleep for as many seconds after each picture has been plotted.
axiscol  If not NULL, then arrows are plotted for projections of the original coordinate axes in these colors.
axislab  Optional labels for the projected axes.
center  Center of the coordinate system to use in projected space. Default is the center of the plotting region.
radius  Relative size of the arrows.
minradius  Minimum radius of arrows to include.
asp, ...  Passed on to randomTourMatrix and from there to plot.
Details

Two random locations are chosen, and data then projected onto hyperplanes which are orthogonal
to step vectors interpolating the two locations. The first two coordinates of the projected data are
plotted. If directions is larger than one, then after the first steps plots one more random location
is chosen, and the procedure is repeated from the current position to the new location, etc..

The whole procedure is similar to a grand tour, but no attempt is made to optimize subsequent
directions, randomTour simply chooses a random direction in each iteration. Use rggobi for the
real thing.

Obviously the function needs a reasonably fast computer and graphics device to give a smooth
impression, for x11 it may be necessary to use type="Xlib" rather than cairo.

Author(s)

Friedrich Leisch

Examples

```r
if(interactive()){
  par(ask=FALSE)
  randomTour(iris[,1:4], axiscol=2:5)
  randomTour(iris[,1:4], col=as.numeric(iris$Species), axiscol=4)

  x <- matrix(runif(300), ncol=3)
  x <- rbind(x, x+1, x+2)
  cl <- cclust(x, k=3, save.data=TRUE)

  randomTour(cl, center=0, axiscol="black")

  ## now use predicted cluster membership for new data as colors
  randomTour(cl, center=0, axiscol="black",
            data=matrix(rnorm(3000, mean=1, sd=2), ncol=3))
}
```

shadow

Cluster shadows and silhouettes

Description

Compute and plot shadows and silhouettes.

Usage

```r
## S4 method for signature 'kccasimple'
shadow(object, ...)
## S4 method for signature 'kcca'
Silhouette(object, data=NULL, ...)
```
Arguments

object  an object of class "kcca" or "kccasimple".
data  data to compute silhouette values for. If the cluster object was created with save.data=TRUE, then these are used by default.

... currently not used.

Details

The shadow value of each data point is defined as twice the distance to the closest centroid divided by the sum of distances to closest and second-closest centroid. If the shadow values of a point is close to 0, then the point is close to its cluster centroid. If the shadow value is close to 1, it is almost equidistant to the two centroids. Thus, a cluster that is well separated from all other clusters should have many points with small shadow values.

The silhouette value of a data point is defined as the scaled difference between the average dissimilarity of a point to all points in its own cluster to the smallest average dissimilarity to the points of a different cluster. Large silhouette values indicate good separation.

The main difference between silhouette values and shadow values is that we replace average dissimilarities to points in a cluster by dissimilarities to point averages (=centroids). See Leisch (2009) for details.

silhouette

Examples

data(Nclus)
set.seed(1)
c5 <- cclust(Nclus, 5, save.data=TRUE)
c5
plot(c5)

## high shadow values indicate clusters with *bad* separation
shadow(c5)
plot(shadow(c5))

## high Silhouette values indicate clusters with *good* separation
Silhouette(c5)
plot(Silhouette(c5))
Description

Shadow star plots and corresponding panel functions.

Usage

```
shadowStars(object, which=1:2, project=NULL,
            width=1, varwidth=FALSE,
            panel=panelShadowStripes,
            box=NULL, col=NULL, add=FALSE, ...)
```

```
panelShadowStripes(x, col, ...)
panelShadowViolin(x, ...)
panelShadowBP(x, ...)
panelShadowSkeleton(x, ...)
```

Arguments

- `object` an object of class "kcca"
- `which` index numbers of dimensions of (projected) input space to plot.
- `project` projection object for which a `predict` method exists, e.g., the result of `prcomp`.
- `width` width of vertices connecting the cluster centroids.
- `varwidth` logical, shall all vertices have the same width or should the width be proportional to number of points shown on the vertex?
- `panel` function used to draw vertices.
- `box` color of rectangle drawn around each vertex.
- `col` a vector of colors for the clusters.
- `add` logical, start a new plot?
- `...` passed on to panel function.
- `x` shadow values of data points corresponding to the vertex.

Details

The shadow value of each data point is defined as twice the distance to the closest centroid divided by the sum of distances to closest and second-closest centroid. If the shadow values of a point is close to 0, then the point is close to its cluster centroid. If the shadow value is close to 1, it is almost equidistant to the two centroids. Thus, a cluster that is well separated from all other clusters should have many points with small shadow values.

The neighborhood graph of a cluster solution connects two centroids by a vertex if at least one data point has the two centroids as closest and second closest. The width of the vertex is proportional to...
the sum of shadow values of all points having these two as closest and second closest. A shadow
star depicts the distribution of shadow values on the vertex, see Leisch (2009) for details.

Currently four panel functions are available:

- `panelShadowStripes`: line segment for each shadow value.
- `panelShadowViolin`: violin plot of shadow values.
- `panelShadowBP`: box-percentile plot of shadow values.
- `panelShadowSkeleton`: average shadow value.

**Examples**

data(Nclus)
set.seed(1)
c5 <- cclus(Nclus, 5, save.data=TRUE)
c5
plot(c5)

shadowStars(c5)
shadowStars(c5, varwidth=TRUE)

shadowStars(c5, panel=panelShadowViolin)
shadowStars(c5, panel=panelShadowBP)

## always use varwidth=TRUE with panelShadowSkeleton, otherwise a few
## large shadow values can lead to misleading results:
shadowStars(c5, panel=panelShadowSkeleton)
shadowStars(c5, panel=panelShadowSkeleton, varwidth=TRUE)
stepFlexclust  

Run Flexclust Algorithms Repeatedly

Description

Runs clustering algorithms repeatedly for different numbers of clusters and returns the minimum within cluster distance solution for each.

Usage

    stepFlexclust(x, k, nrep=3, verbose=TRUE, FUN = kcca, drop=TRUE, 
                   group=NULL, simple=FALSE, save.data=FALSE, seed=NULL, 
                   multicore=TRUE, ...)  

    stepcclust(...)  

    ## S4 method for signature 'stepFlexclust,missing'
    plot(x, y, 
         type=c("barplot", "lines"), totaldist=NULL, 
         xlab=NULL, ylab=NULL, ...)  

    ## S4 method for signature 'stepFlexclust'
    getModel(object, which=1)

Arguments

- x, ...  
  passed to kcca or cclust.
- k  
  A vector of integers passed in turn to the k argument of kcca.
- nrep  
  For each value of k run kcca nrep times and keep only the best solution.
- FUN  
  Cluster function to use, typically kcca or cclust.
- verbose  
  If TRUE, show progress information during computations.
- drop  
  If TRUE and K is of length 1, then a single cluster object is returned instead of a "stepFlexclust" object.
- group  
  An optional grouping vector for the data, see kcca for details.
- simple  
  Return an object of class kccasimple?
- save.data  
  Save a copy of x in the return object?
- seed  
  If not NULL, a call to set.seed() is made before any clustering is done.
- multicore  
  If TRUE, use mclapply() from package parallel for parallel processing.
- y  
  Not used.
- type  
  Create a barplot or lines plot.
- totaldist  
  Include value for 1-cluster solution in plot? Default is TRUE if K contains 2, else FALSE.
- xlab, ylab  
  Graphical parameters.
- object  
  Object of class "stepFlexclust".
- which  
  Number of model to get. If character, interpreted as number of clusters.
Details

stepcclust is a simple wrapper for stepFlexclust(..., FUN=cclust).

Author(s)

Friedrich Leisch

Examples

data("Nclus")
plot(Nclus)

## multicore off for CRAN checks
c11 = stepFlexclust(Nclus, k=2:7, FUN=cclust, multicore=FALSE)
c11

plot(c11)

# two ways to do the same:
getModel(c11, 4)
c11[[4]]

opar=par("mfrow")
par(mfrow=c(2,2))
for(k in 3:6){
  image(getModel(c11, as.character(k)), data=Nclus)
  title(main=paste(k, "clusters"))
}
par(opar)

stripes

Stripes Plot

Description

Plot distance of data points to cluster centroids using stripes.

Usage

stripes(object, groups=NULL, type=c("first", "second", "all"),
beside=(type!="first"), col=NULL, gp.line=NULL, gp.bar=NULL, gp.bar2=NULL, number=TRUE, legend=!is.null(groups),
ylim=NULL, ylab="distance from centroid",
margins=c(2,5,3,2), ...)
Arguments

- `object`: an object of class "kcca".
- `groups`: grouping variable to color-code the stripes. By default, cluster membership is used as `groups`.
- `type`: plot distance to closest, closest and second-closest or to all centroids?
- `beside`: logical, make different stripes for different clusters?
- `col`: vector of colors for clusters or groups.
  - `gp.line`, `gp.bar`, `gp.bar2`: graphical parameters for horizontal lines and background rectangular areas, see `gpar`.
- `number`: logical, write cluster numbers on x-axis?
- `legend`: logical, plot a legend for the groups?
- `ylim`, `ylab`: graphical parameters for y-axis.
- `margins`: margin of the plot.
- `...`: further graphical parameters.

Details

A simple, yet very effective plot for visualizing the distance of each point from its closest and second-closest cluster centroids is a stripes plot. For each of the k clusters we have a rectangular area, which we optionally vertically divide into k smaller rectangles (beside=TRUE). Then we draw a horizontal line segment for each data point marking the distance of the data point from the corresponding centroid.

Examples

```r
bw05 <- bundestag(2005)
bavaria <- bundestag(2005, state="Bayern")

set.seed(1)
c4 <- cclust(bw05, k=4, save.data=TRUE)
plot(c4)

stripes(c4)
stripes(c4, beside=TRUE)

stripes(c4, type="sec")
stripes(c4, type="sec", beside=FALSE)
```
stripes(c4, type="all")

stripes(c4, groups=bavaria)

### ugly, but shows how colors of all parts can be changed
library("grid")
stripes(c4, type="all",
gp.bar=gpar(col="red", lwd=3, fill="white"),
gp.bar2=gpar(col="green", lwd=3, fill="black"))

**volunteers**

**Motivation of Australian Volunteers**

**Description**

Part of an Australian survey on motivation of volunteers to work for non-profit organisations like Red Cross, State Emergency Service, Rural Fire Service, Surf Life Saving, Rotary, Parents and Citizens Associations, etc..

**Usage**

data(volunteers)

**Format**

A data frame with 1415 observations on the following 21 variables: age and gender of respondents plus 19 binary motivation items (1 applies/ 0 does not apply).

- **GENDER**  Gender of respondent.
- **AGEG**  Age group, a factor with categorized age of respondents.
- **meet.people**  I can meet different types of people.
- **no.one_else**  There is no-one else to do the work.
- **example**  It sets a good example for others.
- **socialise**  I can socialise with people who are like me.
- **help.others**  It gives me the chance to help others.
- **give.back**  I can give something back to society.
- **career**  It will help my career prospects.
- **lonely**  It makes me feel less lonely.
- **active**  It keeps me active.
- **community**  It will improve my community.
- **cause**  I can support an important cause.
- **faith**  I can put faith into action.
- **services**  I want to maintain services that I may use one day.
children  My children are involved with the organisation.
good job  I feel like I am doing a good job.
benefited  I know someone who has benefited from the organisation.
network  I can build a network of contacts.
recognition  I can gain recognition within the community.
mind off  It takes my mind off other things.
