Package ‘globals’

October 12, 2018

Version 0.12.4
Depends R (>= 3.1.2)
Imports codetools
Title Identify Global Objects in R Expressions
Description Identifies global (“unknown” or “free”) objects in R expressions by code inspection using various strategies, e.g. conservative or liberal. The objective of this package is to make it as simple as possible to identify global objects for the purpose of exporting them in distributed compute environments.

Index 6
**cleanup.Globals**  
*Drop certain types of globals*

**Description**
Drop certain types of globals

**Usage**
```r
## S3 method for class 'Globals'
cleanup(globals, drop = c("missing", "base-packages"),
       ...)  
```

**Arguments**
- `globals` A `Globals` object.
- `drop` A character vector specifying what type of globals to drop.
- `...` Not used

---

**findGlobals**  
*Get all global objects of an expression*

**Description**
Get all global objects of an expression

**Usage**
```r
findGlobals(expr, envir = parent.frame(), ..., tweak = NULL,
            dotdotdot = c("warning", "error", "return", "ignore"),
            method = c("ordered", "conservative", "liberal"),
            substitute = FALSE, unlist = TRUE, trace = FALSE)
```

**Arguments**
- `expr` An R expression.
- `envir` The environment from where to search for globals.
- `...` Not used.
- `tweak` An optional function that takes an expression and returns a tweaked expression.
- `dotdotdot` TBD.
**findGlobals**

method          A character string specifying what type of search algorithm to use.
substitute      If TRUE, the expression is substitute(ed), otherwise not.
unlist          If TRUE, a list of unique objects is returned. If FALSE, a list of length(expr) sublists.
trace           TBD.
mustExist       If TRUE, an error is thrown if the object of the identified global cannot be located. Otherwise, the global is not returned.
recursive       If TRUE, globals that are closures (functions) and that exist outside of namespaces ("packages"), will be recursively scanned for globals.
skip            (internal) A list of globals not to be searched for additional globals. Ignored unless recursive is TRUE.

Details

There currently three strategies for identifying global objects.

The method = "ordered" search method identifies globals such that a global variable preceding a local variable with the same name is not dropped (which the "conservative" method would).

The method = "conservative" search method tries to keep the number of false positive to a minimum, i.e. the identified objects are most likely true global objects. At the same time, there is a risk that some true globals are not identified (see example). This search method returns the exact same result as the `findGlobals()` function of the `codetools` package.

The method = "liberal" search method tries to keep the true-positive ratio as high as possible, i.e. the true globals are most likely among the identified ones. At the same time, there is a risk that some false positives are also identified.

With recursive = TRUE, globals part of locally defined functions will also be found, otherwise not.

Value

`findGlobals()` returns a character vector.
`globalsOf()` returns a `Globals` object.

See Also

Internally, the `codetools` package is utilized for code inspections.

Examples

```r
b <- 2
e <- substitute({ a <- b; b <- 1 })

## Will _not_ identify 'b' (because it's also a local)
globalsC <- globalsOf(e, method = "conservative")
print(globalsC)

## Will identify 'b'
globalsL <- globalsOf(e, method = "liberal")
print(globalsL)
```
globalsByName

A representation of a set of globals

Description
A representation of a set of globals

Usage
Globals(object, ...)

Arguments
object A named list.
... Not used.

Value
An object of class Future.

See Also
The globals0f() function identifies globals from an R expression and returns a Globals object.

globalsByName
Locates and retrieves a set of global variables by their names

Description
Locates and retrieves a set of global variables by their names

Usage
globalsByName(names, envir = parent.frame(), mustExist = TRUE, ...)

Arguments
names A character vector of global variable names.
envir The environment from where to search for globals.
mustExist If TRUE, an error is thrown if the object of the identified global cannot be located. Otherwise, the global is not returned.
... Not used.

Value
A Globals object.
packagesOf.Globals

Identify the packages of the globals

Description

Identify the packages of the globals

Usage

```r
## S3 method for class 'Globals'
packagesOf(globals, ...)
```

Arguments

- `globals`: A Globals object.
- `...`: Not used.

Value

Returns a character vector of package names.
